Winding Machine

This machine is built to roll a product previously formed in a non-woven line on a cardboard tube, placed inside. The winder is available with working heights starting from 2000mm up to 5500mm.

Usually this machine is preceded by a cross cutting machine.

This machine is particularly suitable for enough low and flexible layers to be rolled up.

The winder is composed by two \varnothing 408mm rubberized cylinders and two sides adjustable in width that contain the material at the sides while it is being rolled up.

The motorization can be done with a single motor or with one motor per cylinder in order to adjust the speed difference and therefore the shrinking effect on the roll.

The roll change and new roll start operations are done manually by the operator.

All machine drives are controlled by inverters with 1/12 adjustment range.
